IDENTIFIERS	*Fertility

ABSTRACT

This report, largely statistical tables, presents data from the June 1975 Current Population Survey, on the timing and spacing of childbearing and discusses how such data is related to annual measures of fertility. By categorizing women according to their year of birth (birth cohort) or period of first marriage (marriage cohort), in addition to various social and economic characteristics (race, family income and educational level), differences are shown in the tempo of childbearing in various time periods over the 20th century and for women of differing characteristics. Data analyzed by birth cohort examined: teenage marriage and fertility; age at completion of childbearing; interbirth intervals for last and next-to-last child; and differences by level of educational attainment. Data analyzed by marriage cohort examined: recent patterns in interval between first marriage and first birth; racial differences in child-spacing; and spacing of first births related to age at first marriage. A third method of analyzing birth histories, also presented here, is according to the calendar period in which they occurred (birth cohorts of the children). Certain statistical biases of the Current Population Survey data are discussed, particularly in relation to the omission of data on births to single women. (BF)

Trends in Childspacing: June 1975

INTRODUCTION

Annual measures of a Nation's fertility are affected not only by the total number of children women bear during their lifetimes but also by the "tempo" at which those children are born,[1] that is, how early in life childbearing begins as well as the length of the intervals between births. Therefore, if women begin to bear children earlier and more rapidly than women who immediately preceded them, annual fertility rates will undergo a period of rapid increase and will likely attain levels higher than the completed fertility rates of any group of women in their reproductive years during that period. An example of this effect was the "baby boom" after World War II. However, if women begin to delay having children and space them more widely than their predecessors, annual fertility rates will be deceptively low for a period of time, as was the case during the Depression years of the 1930's.[2] The delay in childbearing is a factor which may be partially responsible for current low annual fertility rates.[3]

The information on the timing and spacing of childbearing contained in this report is based on marriage and birth histories obtained in the June 1975 Current Population Survey. Data derived from birth histories and used in conjunction with the mother's date of birth permit the determination of the mother's age at the birth of each of her children. In conjunction with the date of the mother's first marriage, birth histories make possible the study of intervals from time of first marriage to the birth of each child. By categorizing women according to the period of their birth ("birth cohort") or the period of their first marriage ("marriage cohort"), in addition to various social and economic characteristics, differences can be shown in the tempo of childbearing at various periods of time and for women of differing characteristics.

Principal findings discussed in the text of this report are:

- Fewer teenage marriages were reported by women in their twenties than women in their thirties at the time of the survey.
- The percentage of women bearing a child during their teens is lower for women born from 1950 to 1954 than for any 5-year age group of women since those born from 1925 to 1929.
- Although 22 percent of women first married in the period 1970 to 1974 had their first child by 7 months after marriage, which is a relatively high percentage, only 33 percent had their first child by 1 year after marriage, which is less than for any gorup of women first married since 1950 to 1954.
- Among women first married during the 45 years from 1930 to 1974, those married in the period 1955 to 1964 showed the highest percentage becoming mothers by 1 and 2 years after marriage.
- The slowdown in childbearing in recent years is also shown in statistics relating to births occurring in a given period. For example, the median interval from first marriage to first birth was 5 months longer during the 1970 to 1974 period than it was during the 1965 to 1969 period for both Black and White women.
- Median intervals from previous birth for second, third, and fourth births occurring from 1970 to 1974 are greater than in any 5-year period since 1940 to 1944.

BIRTH COHORTS

Teenage marriages and fertility. Since teenage marriages and childbearing are often accompanied by marital instability and problems in childbearing and childrearing,[4] there is special interest in changes and differences in marriage and fertility rates among teenage women. Statistics on early marriage and childbearing are presented in table A.

As of the survey date in June 1975, the youngest 5-year cohort of women to complete their teenage years was born from 1950 to 1954 and was 20.5 to 25.5 years old. These women have had the lowest levels of fertility at age 19.5 (197 children ever born per 1,000 White women and 354 per

---

[1] See Norman B. Ryder, "The Family in Developed Countries," **Scientific American** (September, 1974), pp. 123-132.

[2] See for example, Clyde V. Kiser, Wilson H. Grabill, and Arthur A. Campbell, **Trends and Variations in Fertility in the United States** (Cambridge: Harvard University Press, 1968), pp. 258-264. Different patterns in the timing of childbearing among different birth cohorts of women can lead to statistical anomalies. In 1942 and from 1946 to 1957, with the exception of 1950, the annual total fertility rate for first births was over 1 per woman. The meaning of the statistics is that, if a group of women went through their reproductive life experiencing first births at each year of age at the rates observed in the given year, they would eventually have more than 1 first child per woman. Clearly, the age-specific first birth rates of those years could not be sustained indefinitely. The anomaly of first birth total fertility rates in excess of 1 per woman was caused by older women who had postponed childbearing during the 1930's and the war years "catching up" after the war at the same time that younger women were having children at unusually high rates. See Robert L Heuser, **Fertility Tables for Birth Cohorts by Color: United States, 1917-73**, DHEW Publication No. (HRA) 76-1152 (Washington, D.C. 1976), tables 1A and 4A.

[1] Numbers of women and percent first married are based on June 1976 Current Population Survey; data on births are from the June 1975 Current Population Survey.

[2] Data adjusted for the part of the cohort that has not reached the stated age; see text for method of adjustment.

Source: Table 2 of this report and unpublished Current Population Survey data.

1,000 Black women) of any cohort of women born since 1930. By way of contrast, women born in the 10 years from 1935 to 1944, many of whom were contributors to the "baby boom" of the 1950's and early 1960's, had the highest rates of teenage childbearing of any cohort shown in table A. The continuing decline in early childbearing after the peak reached by women born from 1935 to 1944 is reflected in the percentage of women who had a child by the middle of their 20th year. About 16 percent of the White women and 24 percent of the Black women born from 1950 to 1954 had borne one or more children by age 19.5 years (figure 1). In the "boom" cohort born from 1935 to 1944, 21 percent of White women and 40 percent of Black women had at least one child by the age of 19.5

In assessing the statistics cited above, it should be noted that there is a systematic bias in the fertility measures for birth cohorts of women. In this section and in tables 1 through 10 the base for calculating average numbers of children is all women born in the specified calendar period. However, since women who were single as of the survey date were not asked about their childbearing experience, the numerator of the rates is children born to ever-married women. Thus, the published rates are biased toward underestimating true cohort rates. This bias should be somewhat more pronounced for younger cohorts, where a substantial proportion of the women were still single at the time of the survey. For example, about 65 percent of the women born from 1950 to 1954 had been married as of the survey date, whereas 94 percent of those born from 1940 to 1944 had been married. During the remainder of their lifetimes after 1975, an additional 25 to 30 percent of the 1950 to 1954 birth cohort of women can be expected to marry for the first time. Some of these women will have one or more children premaritally, in which case their children were omitted from the June 1975 survey design. This has the effect of underestimating the true cohort rate.

It is not possible to make a direct assessment of the size of this bias. It is known, however, that the illegitimacy rate for White women 15 to 19 years old continued to rise through 1975 and that the corresponding rate for Black women remained at a high level, although declining somewhat since 1972. Moreover, 7.3 percent of all births to White women were classified as illegitimate in 1975; among births to Black women 48.8 percent were so classified.[5] Over half of all illegitimate births to both White and Black women in 1975 occurred to women under 20 years of age. On the other hand, many women who bore children premaritally, even those in the birth cohort of 1950 to 1954, had married by the time of the survey and their premarital children were, in principle, included in the tabulations.

Differences in teenage childbearing are quite naturally associated with differences in percentages of women marrying during their teens. For example, 33 percent of White women born in the early 1950's had married for the first time by the middle of their 20th year; this is a decline of about 8 percentage points from the average (41 percent) for White women born in 1935 to 1939. The corresponding percentages for Blacks were 27 percent for the younger women and 48 percent for the older women. In fact, the relative decline in teenage marriage and childbearing among recent birth cohorts of women is sharper among Black women than among White women. The movement away from early marriage, which is evident among women now in their twenties, has clearly resulted in a generally less rapid entrace into motherhood, as compared with women in their thirties at the time of the survey.

A faster tempo of childbearing is usually associated with higher ultimate fertility levels. Thus, groups of women who reported higher rates of children ever born during their teens and early twenties are very likely to complete their childbearing with higher rates. However, this is not always the case, as is shown in table 1. Women of all races in the 1935 to 1939 birth cohort had an average of 1.7 children per woman by age 25.5 years; while women born in the 1930 to 1934 cohort averaged only 1.6 children by the saem time in life. By age 38.5, however, the lead was reversed--the older group of women averaged 3.1 children per woman and the younger only 2.9 children. It now appears likely that women born from 1930 to 1934 will complete their childbearing with an average number of children near 3.2 per woman, and will have the distinction of having the highest completed fertility rates of any cohorts born since the late 1880's.[6] It is highly unlikely that the fertility of these women, now in their early forties, will be equalled or surpassed in the foreseeable future.

Age at completion of childbearing. Tables 17 through 19 present data on the ages of women at completion of childbearing for birth cohorts of women who were in their late thirties older at the time of the survey. Although the physical capacity to bear children usually ceases for a woman sometime during her middle or late forties, most women will have completed childbearing long before that age. Data from the survey indicate that of all women who become mothers, 90 percent or more have their last child by age 40 and over 70 percent have their last child by age 35.[7] The youngest cohort of women, shown in tables 17 through 19, born from 1930 to 1939, was approximately 35 to 45 years old at the time of the survey. Because a sizable minority of these women will probably bear another child, the experience of this cohort is not fully comparable to that of older cohorts.

[6] For completed and near-completed cohort fertility rates, see Heuser, **Fertility Tables**, table 6A.

[7] U.S. Bureau of the Census, **Current Population Reports**, Series P-20, No. 263, "Fertility Histories and Birth Expectations of American Women: June 1971," table 12.

Comparisons between the cohorts of 1920 to 1929 and 1910 to 1919 will be reasonably valid, as all but a negligible fraction of the women born in the 1920's have had their last child by 1975.

The median ages at completion of childbearing, which are summarized in table B, indicate that half of the women of all races who are mothers of one or more children have their last child by age 30 or 31. Moreover, by age 40 over 90 percent of all mothers born from 1910 to 1919 or 1920 to 1929 had completed their childbearing experience (table 17). However, as is only reasonable, there are substantial differences in the ages at which mothers have their last child, depending on how many children they have. For example, the median age at completion of childbearing is about 26 or 27 years for the relatively few women who have only 1 child; for women with 5 or more children the median age is 36 or 37 years (table B). Mothers with 2 to 4 children tend to complete childbearing at ages between the extremes just cited.

Although some women born from 1930 to 1939 have not yet completed their childbearing years, it now appears that for White women and Black women born in this period, differences in the median age at the birth of the last child will be minimal (tables 18 and 19). The median for White mothers of all parities was 29.0 years as of the survey date, compared with 29.7 for Blacks; this apparent difference is well within the bounds of sampling error. Moreover, there is no consistent pattern of Black-White differences by parity.

Interbirth intervals for the last and the next-to-last children. For children of a given birth order, spacing from the previous child, or from their mothers' first marriages, appears to depend to a great extent on whether or not they are the last child born to their mother. For instance, among the second children of women born from 1920 to 1929 (who had, with very few exceptions, completed childbearing by June 1975), those children who were their mothers' last were born at a median interval of about 42 months after the birth of the first child. However, the median interval from first birth for those who were the second of three children was only 30 months (figure 2). Comparable differences are shown for third and fourth children of women born from 1920 to 1929, where the median spacing interval for last children of a given birth order is about 1 year longer than for children of the same birth order who were next to last.

To what extent these differences in interbirth spacing intervals are due to conscious choices of individual couples or to factors beyond their control cannot be determined from the Current Population Survey data. Couples who consciously plan to have a certain number of children may be inclined to space them differently, depending on how many

Table B. Median Age at Completion of Childbearing, for Ever-Married Mothers Born From 1900 to 1929: June 1975

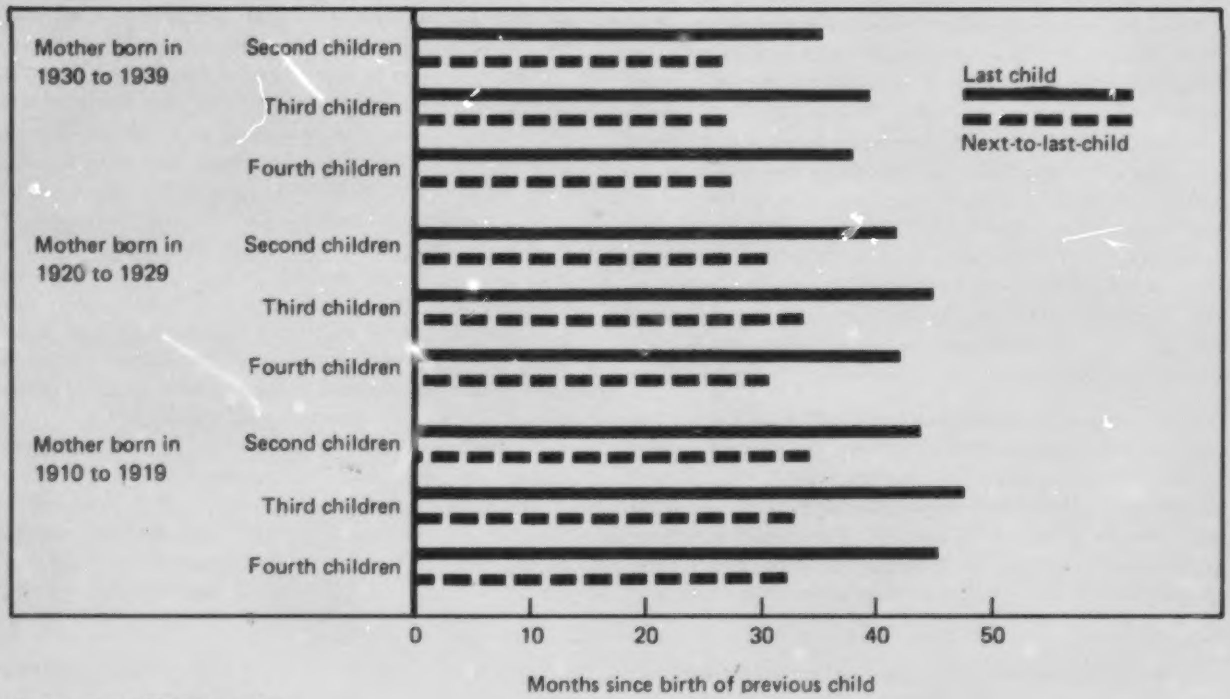
(Data limited to women ever married)



Source: Table 25 of this report.

children they plan to have. For instance, a couple who plans to have three children may be able to plan for longer spacing between second and third children than a couple planning on four children. Declining fecundity as women age and the greater likelihood that the last child is unplanned are other plausible reasons why the last interbirth interval is often substantially longer than the next-to-last interval.

The tendency for women who have many children to have them more rapidly is shown in table 21. Women born from 1925 to 1929 had a median spacing interval of 41 months from first to second child if the second child was the last one. However, the corresponding median was 25 months for women who went on to have one or more children after the second. The different spacing patterns of children of a given birth order, depending on whether a child is the mother's last or next-to-last, does not appear to be closely related to the level of educational attainment. Regardless of the mothers' level of educational attainment, as shown in tables 20 to 24, first to fifth children who are last children are generally spaced at greater intervals than children of the same birth orders who are next-to-last children. There may be some association between educational attainment and the size of the differences in median spacing intervals for last and next-to-last children of a given birth order, but no consistent pattern clearly emerges.

Differences by level of educational attainment. It is difficult to make valid comparisons of fertility and child-spacing patterns by level of educational attainment for women who have not yet completed most of their child-bearing experience. If, in general, a woman completes her education before entering marriage and forming a family, then the fact that a woman spends more years in the educational process will usually mean that she has less time available during her reproductive period for bearing children. This alone is a likely factor acting to reduce the fertility of better-education women.

Table C shows a compromise between making no comparisons of actual fertility by levels of educational attainment and making comparisons at ages when the differences in rates are largely due to differing amounts of time spent in school. All women in the four cohorts shown were at least 30.5 years old at the time of the June 1975 Current Population Survey. In that survey, married women 30 to 34 years old reported that they had completed 93 percent of their expected lifetime childbearing; married women of the same age with 1 or more years of college education reported that 87 percent of their expected lifetime fertility had been completed.[8] Thus, the data in table C are reasonably comparable both within cohorts and between cohorts, especially since they are limited to first, second, and third order births.

---

[8] U.S. Bureau of the Census, *Current Population Reports*, Series P-20, No. 301, "Fertility of American Women: June 1975," table 9.

Rates of first to third births combined, as of age 30.5 years, bear the usual inverse relationship between educational attainment and fertility within each of the cohorts shown in table C. For the most part, average numbers of first and second children combined show little difference between women who completed 4 years of high school and those who did not. Differences in third birth rates for these two groups, however, are significantly different. For example, women born from 1930 to 1934 who did not graduate from high school had an average of 1,591 first and second births per 1,000 women, wheras those who completed high school but did not go on to college had a corresponding average of 1,615. However, the respective third birth averages were 552 and 453. On the other hand, significant differences between women with some college and those with no college education occur both for first and second births combined and for third births. Continuing with the example of women born in 1930 to 1934, those who had completed 1 or more years of college averaged 1,416 first and second births per 1,000 women, as opposed to corresponding averages of 1,591 and 1,615 for the two groups of women with no college; the third birth averages for college education women was 361 per 1,000 women, versus averages of 552 and 453 for the other groups.

The overall low level of fertility to age 30.5 years for the 1940 to 1944 birth cohort of women, relative to the cohorts of 1930 to 1934 and 1935 to 1939, is not observed among women who did not complete 4 years of high school education. However, among women who complete 1 or more years of college education, those born in 1940 to 1944 had an average of about 300 fewer first to third order births per 1,000 women than did those born in the two preceding 5-year birth cohorts.

Table C. Births of First, Second, and Third Order by Age 30.5 Years, by Years of School Completed: June 1975

(Single women counted as childless)

Subject	Year of mother's birth		
	1940 to 1944	1935 to 1939	1930 to 1934

MARRIAGE COHORTS

A great amount of research has focused on the social and medical consequences of teenage childbearing, as well as on the likely outcome of marriages precipitated by a premarital pregnancy, especially if the bride and groom are very young.[9] But even for women who conceive and bear their children within marriage, different patterns of spacing children can have various social and economic effects on the life of the family. A longer period of time from first marrying to the birth of the first child may provide a young couple with an opportunity to adjust to a new manner of living and to build up financial reserves. Other couples might prefer to have their children early in marriage in order to condense the years in which close supervision of young children is required, thus allowing both parents to pursue careers outside the home after a reasonably short time. However, early and/or "condensed" childbearing often does not occur within the context of family planning, but rather results from unplanned pregnancies and is the forerunner of more children being born to the couple.

Tables 26 to 35 of this report present tabulations of births according to the number of months since the mother's first marriage. In order to show differences in spacing patterns in different time periods, women are classified according to the 5-year period in which they first married. For purposes of comparison within a group according to certain characteristics, each 5-year "marriage cohort" has also been categorized by the woman's age at time of first marriage (tables 30 to 32) and by her years of school completed (tables 33 to 35).

Recent patterns in the interval between first marriage and first birth. The marriage cohort of 1970 to 1974, the most recent shown in tables D and 26, displays some interesting patterns in the spacing of first children. About 22 percent of the women first married in this period had borne their first child by 7 months after first marriage, a figure which includes almost 10 percent who gave birth before marriage. A child born at any time up to 7 months after first marriage was almost certainly conceived premaritally.[10] The figure of 22 percent, which has remained relatively constant for the three cohorts married since 1960, contrasts sharply with the corresponding percentages for the cohorts married prior to 1950. On the other hand, the 1970 to 1974 marriage cohort shows the lowest percentage (33 percent) of women bearing a child within 1 year of marriage for any cohort of women since those first married from 1950 to 1954. A projection of this cohort's experience suggests that after 2 years of marriage less than half the women in the cohort will have borne a child. One of the interesting and important aspects of future surveys on birth histories will be to establish whether or not, and at what pace, women first married in 1970 to 1974 eventually make up for their relative delay in becoming mothers.

Women married in the years 1955 to 1959 and 1960 to 1964 appear to have made a rapid start on childbearing; about 43 percent of these women had borne their first child by 1 year after first marriage. By 2 years after first marriage, about 68 percent had borne one or more children. These percentages are significantly higher than the corresponding percentages for the other cohorts shown in table D. Nevertheless, judging from the total births per 1,000 women as of June 1975, women married in 1955 to 1959 and 1960 to 1964 will not complete their fertility with as high an average number of children ever born as women married in 1950 to 1954, who, after 20 years of marriage, have averaged 3.2 children per woman (table 26).[11]

Racial differences in childspacing. Substantial differences in childspacing patterns between White women and Black women are shown in the data of table D. Among women married since 1960 about 36 percent of the Black women had borne a child before first marriage, whereas 5 to 6 percent of White women had done so. By 1 year after first marriage, more than 60 percent of the Black women had borne their first child; the corresponding statistics for White women ranged from about 41 percent for women married in 1960 to 1964 to about 30 percent for the cohort of 1970 to 1974. Differences similar in direction are found among cohorts of Black women and White women married in the 1930's and 1940's, whose reproductive years are now completed (with the possible exception of a few women who married at young ages in the late 1940's).

It may be surprising that childlessness is more prevalent among Black women than among White women. About 12 percent of White women married in the 1930's and 1940's remained childless (table 27); among Black women, the corresponding statistic was approximately 19 percent (table 28). White women first married in the 1940's have averaged about 2.8 children per woman; those married in the 1930's averaged about 2.5 children per woman. Black women first married in those same periods completed their fertility with an average of 3.3 to 3.4 children per woman. Thus, although

Menken, "Teenage Childbearing: Its Medical Aspects and Implications for the United States Population," in Commission Population Growth and the American Future, **Demographic and Social Aspects of Population growth**, Charles F. Westoff and Robert Parke, Jr., eds. (Washington, D.C., 1972), pp. 331-353.

[10] Because birth and marriage are dated by month and year of the event (and not by day as well), a few children born almost 8 months after their mothers' first marriages will have been categorizes as being born 7 months after the mothers' marriages. It is likely that a few premature babies, conceived within marriage, are included among those born 7 months after their mothers' first marriages.

[11] This judgment is based on cohort comparisons after 180 and 240 months of marriage. Some women in all marriage cohorts from 1950 to 1964 are still in their reproductive years. However, all have been married sufficiently long to permit a reasonably sound estimate of completed fertility.

Black women in the marriage cohorts from 1930 to 1949 started childbearing earlier and attained higher levels of completed fertility, they also have had higher levels of childlessness than White women who first married in the same period. Although it is too early to predict that the same difference among the races will prevail among young marriage cohorts, some evidence in tables 27 and 28 points in that direction.

Spacing of first births related to age at first marriage. A woman's age when she first marries is also associated with the time interval between the date of first marriage and the birth of her first child. The data in table 30 show that in each marriage cohort, women who married in their middle teens (14 to 18 years) tended to bear their first child much sooner in relation to their marriage date than did women who first married after age 18. Some, but not all, of the earlier onset

Source: Tables 26 to 28 of this report.

of childbearing among women who married very young is due to a greater proportion of the women marrying because of a premarital pregnancy. The validity of this assumption is shown in the proportions of first children borne within 7 months of marriage, a point at which most births will have been conceived before marriage. In each of the cohorts shown in table 30 women who first married at ages 14 to 18 years have had higher proportions of first children born at the end of 7 months of marriage than did women of the same cohort who first married later in life. Moreover, the difference appears to be increasing among more recent cohorts. Among women married in 1970 to 1974 about 32 percent of those married at ages 14 to 18 years had a child by 7 months after marriage, as compared with about 18 percent for women first married after 18 years of age; among women first married in 1965 to 1969 the comparable percentages were 30 and 20. However, for women first married in 1940 to 1949 the percentage of women who had borne a child by 7 months after marriage was comparatively low, 14 and 10 percent, respectively, for women first married at 14 to 18 years of age and for those first married after age 18.

In this context, however, it is perhaps surprising to note that the incidence of childbirth before first marriage appears to be highest among women who married at 22 years of age or more. This is consistent, however, with the findings in other studies that women who bear a child before marriage tend to marry later than those who premaritally conceive but marry before the child's birth or those who both conceive and bear their first child within marriage.[13]

BIRTHS IN CALENDAR PERIODS

Another way of analyzing birth histories is to categorize the births according to the calendar period in which they occurred, that is, according to birth cohorts of the children. Tables 36 through 54 present data in this manner. The "spacing" factor for births grouped by calendar periods can be the age of the mother at the time of the birth (as in tables 1 through 25 for birth cohorts of women), or the interval from the mother's first marriage (as in the marriage cohort tables 26 to 35, if the births are limited to those occurring to ever-married women), or the interval from the birth of the previous child for second and higher order births. The latter two methods of measuring childspacing are employed in this report, that is, interval from the mother's first marriage (tables 36 through 45) and interval from the previous child (tables 46 through 54).

The presentation of births in calendar periods according to the interval from the mother's first marriage may look quite similar to the presentation in terms of marriage cohorts of women. However, births tabulated according to the calendar period of the mother's first marriage lack a reference to a defined time period. Some will have occurred sometime before the mother's marriage, and thus may or may not have occurred in the same 5-year period as the mother's marriage. Other births, occurring at increasing intervals after the mother's marriage are not definable as occurring in any specified year or group of years.

Another difference in presenting data according to the birth cohort of the child rather than according to the birth or marriage cohort of the mother is that in the former method there is no truncation of the dates for recent cohorts due to incomplete experience. By definition, all children who will ever be born in 1970 to 1974 were already born as of the survey date and the circumstances of those births can be known. On the other hand, events that are to occur at age 25 to a women born in 1952 were not even knowable in June 1975; the same is true with respect to events that are to occur at 10 years after first marriage to a women first married in 1968. Thus, in tables 36 through 54, it is possible to make valid intercohort comparisons for all cohorts of children at all spacing intervals.

Interval from marriage to first and second births. Data from the June 1975 Current Population Survey clearly indicate that there has been a turn-around during the years 1970 to 1974 in the previous trend toward a more rapid entrance into parenthood after first marriage, and the turnaround appears to be true for both Black women and White women. The period in recent times in which first births occurred soonest in relation to first marriage was during the early to mid 1960's, when the median interval for White women was about 14 months after first marriage and about 4 months for Black women (figure 3). The median interval from marriage to first birth for births occurring in 1970 to 1974 showed an increase of about 5 months over the previous 5-year period for both Blacks and Whites.

Another way of assessing the recent "delay" in having first children is to compare percentages of first births occurring at given intervals (figure 4). In 1970 to 1974, 58 percent of all first births to White women had occurred by 24 months after the mothers first married. This is almost 12 percentage points less than the corresponding figure for births in 1965 to 1969 and 16 points less than that for births in 1960 to 1964. About 74 percent of first births to Black women in 1970 to 1974 occurred by the time the mothers had been in a first marriage for 2 years or less, whereas the corresponding figure for births occurring to Black women in the 1960's was 86 percent.

The percentage of first births occurring before marriage of by 6 months after first marriage appears to have declined among Black women in 1970 to 1974 from the previous 5-year period. This decline seems to be accounted for almost entirely by a reduction in births occurring before the mother's first marriage, rather than in a decline in premarital conceptions subsequently legitimated by marriage. Among White women, however, the percentage of births occurring

within 6 months of the mother's first marriage has remained almost constant during the last 10 years and at levels higher than those which prevailed earlier.

Among White women the spacing of second births in relation to first marriage also shows a "stretch-out" in the years 1970 to 1974, relative to births in the previous 15 years (figure 3). The median interval from first marriage to the birth of the second child in 1970 to 1974 was about 52 months, an increase of almost half a year over the period 1965 to 1969 and of about 9 months over the period 1960 to 1964. In 1970 to 1974 the median interval between first marriage and second births to Black women was about 31 months, almost a year and three quarters less than for White women. Still, the median for Blacks showed an increase of about 7 months over the corresponding median for the period 1965 to 1969.

Interbirth spacing. Tables 46 to 54 show comparative patterns of childspacing in terms of intervals from one birth to the next, for births occurring in specified calendar periods. Among women of all races combined the median spacing intervals for second and third births during 1970 to 1974 have been greater than in any 5-year period since at least 1940 to 1944 (table E). The same appears to be true for fourth births as well, although the statistical significance of the difference between fourth births in 1970 to 1974 and those in 1965 to 1969 indicates that this difference is somewhat more likely to be due to sampling variability.

This definite slow-down in the tempo of childbearing during the late 1960's and early 1970's is almost surely related, among other factors, to an increasing acceptance and usage of modern and effective methods of contraception[13], as well as to lowered levels of lifetime fertility expected by young couples,[14] who are the parents of most of the children born in any given period. The ability to limit fertility effectively and the intention of having relatively few children have likely led many couples to a more deliberate and careful spacing of the children they do have.

Comparison of births from the current population survey with births from vital statistics. Since the June 1975 Current Population Survey (CPS) catalogs births according to year of occurrence, the data collected in this cross-sectional survey can be compared with the data from birth registrations,

which are compiled annually by the National Center for Health Statistics. Both sources of data provide national estimates of births, although from quite different perspectives. Birth registrations are the records of vital events as they occur. They are estimated to be over 99 percent complete for White births since the early 1950's and 98 percent or more complete for "all other" births since 1965.[15]

Birth histories from the June 1975 CPS have several inherent biases as an estimator for all births occurring in the United States. One of the most serious of these is that only ever-married women were surveyed. Thus, all births to women who were single as of the survey date are omitted in principle, although some single women with children living with them may have been reported as having been married at the time of the child's birth. (Births occurring before first marriage to women ever married as of June 1975 were included in principle, although some women may have "adjusted" dates of marriage and child birth to "legitimate" a child born before the mother's marriage.) Another source of bias, less serious for recent births than for those at an earlier date, is that estimates of births based on the CPS depend on the reports of women who survive to the survey date. Thus, children born to women who subsequently died prior to the survey are excluded from CPS estimates. Additional sources of bias in CPS estimates are: (1) the data are limited to noninstitutionalized women; (2) children born

to current residents are counted, even if those children were born outside the United States; (3) the dating of births is dependent on retrospective reports, which in some households are accepted from proxy respondents.

Table F presents a comparison of births estimated by the CPS and by the system of birth registrations for two recent 5-year periods, 1965 to 1969 and 1970 to 1974. On the whole, CPS estimates of White births appear very close to those of birth registrations for the two periods in question, although the CPS estimate for fifth and higher order births in 1970 to 1974 is suspiciously higher than the estimate from birth registrations. CPS estimates of Black births, however, are substantially below those based on registered births. This discrepancy is attributable, in large part, to the much larger proportion of children born to Black single women who were not asked the question about their fertility to date.[16] (Beginning with the June 1976 CPS, however, all women regardless of marital status are being asked the number of children they have ever borne.)

RELATED REPORTS

Data on birth expectations and fertility from the June 1975 Current Population Survey were published in **Current Population Reports,** Series P-20, No. 301. Data from the same survey on marriage and divorce have been published in **Current Population Reports,** Series P-20, Nos. 297 and 312.

The last pages of this report contain a list of fertility-related **Current Population Reports** both in Series P-20 and in Series P-23. Reports in Series P-20 which show data closely related to the content of this report are nos. 108, 186, 211, 232, and 263. Decennial census reports which contain information on childspacing are: **Census of Population:** 1970, PC(2)-3B, Childspacing and Current Fertility; and **Census of Population:** 1960, PC(2)-3B, Childspacing.

In addition to published reports based on the June 1975 Current Population Survey, a public use file, including both basic labor force data and supplemental marital and fertility history data from the June 1975 survey, is currently available at a cost of $80 per tape reel. In most configurations, the file will consist of 3 reels. For information concerning this data file, contact the Chief, Customer Services Branch, Data User Services Division, Bureau of the Census, Washington, D.C. 20233, telephone (301)-763-2400.

---

[1] Single women (all treated as childless) and ever-married women who remained childless are counted at all ages as having completed their childbearing.

[2] Women who remained childless are counted at all ages as having completed their childbearing.

[3] For purposes of this tabulation, women born in 1930 to 1939 are assumed to have completed their childbearing at 40 years of age. As noted, data are adjusted for the part of the cohort that had not attained age 40.

[4] Data adjusted for the part of the cohort that has not reached the stated age; see text for method of adjustment.

[5] For purposes of this tabulation, women born in 1920 to 1929 are assumed to have completed their childbearing at 45 years of age.

---

[1] Single women (all treated as childless) and ever-married women who remained childless are counted at all ages as having completed their childbearing.

[2] Women who remained childless are counted at all ages as having completed their childbearing.

[3] For purposes of this tabulation, women born in 1930 to 1939 are assumed to have completed their childbearing at 40 years of age. As noted, data are adjusted for the part of the cohort that had not attained age 40.

[4] Data adjusted for the part of the cohort that has not reached the stated age; see text for method of adjustment.

[5] For purposes of this tabulation, women born in 1920 to 1929 are assumed to have completed their childbearing at 45 years of age.

---

[1] Single women (all treated as childless) and ever-married women who remained childless are counted at all ages as having completed their childbearing.

[2] Women who remained childless are counted at all ages as having completed their childbearing.

[3] For purposes of this tabulation, women born in 1930 to 1939 are assumed to have completed their childbearing at 40 years of age. As noted, data are adjusted for the part of the cohort that had not attained age 40.

[4] Data adjusted for the part of the cohort that has not reached the stated age; see text for method of adjustment.

[5] For purposes of this tabulation, women born in 1920 to 1929 are assumed to have completed their childbearing at 45 years of age.

Table 20. SPACING OF FIRST CHILD FROM MOTHER'S FIRST MARRIAGE, BY PARITY AND YEARS OF SCHOOL COMPLETED IN 1975, FOR WOMEN BORN FROM 1920 TO 1939: JUNE 1975

(Civilian noninstitutional population. Data limited to women ever married, with one or more children ever born, and who reported the birth dates of all children. For meaning of symbols, see text)

Allocated by interpolation[4]	6,229	6.4	4,482	5.3	1,667	13.7	580	10.8

---

[1] May be of any race.

[2] Date of birth was asked for a maximum of 5 children. Thus, only women with 5 or fewer children ever born can "fully report" on the birth dates of their children. See also footnote 4 below.

[3] If year of birth was not reported or was out of order for any child, month and year were allocated for all children.

[4] For women with 6 or more children ever born, birth dates for one or more of their children were allocated by a process of linear interpolation, regardless of whether or not data were fully reported for 5 children; see text for a description of the method.

Appendix B

DEFINITIONS AND EXPLANATIONS

Population coverage. The data from the Current Population Survey are for the civilian noninstitutional population of the United States. Because only a small proportion of women are inmates of institutions (less than 1 percent of women 15 to 44 years old being institutionalized), the data for the civilian noninstitutional population have a high degree of comparability with data for the total population.

Children ever born. The question "How many babies has . . . ever had (Do not count still births)?" was asked of all women more than 13 years old and born in 1900 or later who were reported as married (including separated), widowed, or divorced. When asking about children ever born, interviewers were instructed to include children born to the woman before her present marriage, children no longer living, and children away from home as well as children who were still living in the home. It is possible that some never-married mothers living with one or more of their natural children reported themselves as having been married. In addition, many mothers who first married after the birth of one or more children counted those children, as they were expected to do. Nevertheless, data are probably less complete for premarital births than for births after marriage. Single (never-married) women are presumed to be childless for purposes of statistics shown in tables 1 through 10 and 17 through19 of this report.

In filling out the interview schedule, the interviewer entered the number of children ever born from 0 to a terminal category of "10 or more." For purposes of computing the total number of children ever born, the terminal category was counted as 10.

Birth dates of children. The specific month and year of birth were reported for the woman's first three children and her last two children. In tabulation, birth dates were linearly interpolated for any children who were intermediate between the third child and the next-to-last child.

Parity. Parity is the number of children ever born to a woman. Use of the term "parity" e.g., "two parity women," provides a less cumbersome expression than "woman with two children ever born."

Order of birth. The term "order of birth" or "birth order" refers to the sequence of children borne alive by the woman. Thus, it indicates whether the child is the mother's first child ever born her second child, etc. If the woman has twins, one of them is counted before the other, according to the sequence in which they were born.

Last child. This term pertains to the latest child born as of the survey date.

Cohorts of women. Two types of cohorts are shown in this report. A birth cohort is a group of women who were born in a specified calendar period. A marriage cohort is a group of women who first married in a specified calendar period, regardless of any subsequent changes in marital status.

Interval from first marriage. The interval between a woman's first marriage and the birth of any one of her children was derived by subtracting the date of marriage of the woman from the date of birth of the child. Both dates were in terms of month and year. If the birth date of the child was prior to that of the mother's first marriage, the child was categorized as being born "before first marriage." If the child's birth date was the same as or later than the date of the mother's first marriage, the child was categorized as being born at started intervals "after first marriage."

Interval between births of children. The interval between the births of two successive children was derived by subtracting the birth date of the earlier child listed from that of the later child. Both dates were in terms of month and year of birth.

Marital status. Data refer to present marital status. All women may be categorized as either single (never married) or ever married, the latter consisting of women who are married, widowed, or divorced.

Household. A household consists of all the persons who occupy a housing unit. A house, an apartment or other group of rooms, or a single room, is regarded as a housing unit when it is occupied or intended for occupancy as separate living quarters; that is, when the occupants do not live and eat with any other persons in the structure and there is either (1) direct access from the outside or through a common hall or (2) a kitchen or cooking equipment for the exclusive use of the occupants.

A household includes the related family members and all the unrelated persons, if any, such as lodgers, foster children, wards, or employees who share the housing unit. A person living alone in a housing unit, or a group of unrelated persons sharing a housing unit as partners, is also counted as a household. The count of households excludes group quarters.

Family. A family is defined as a group of two or more persons residing together who are related by blood, marriage, or adoption. A lodger and his wife or an employee and his wife, both residing in the household, are considered as separate families. On the other hand, a person living alone or with one or more unrelated persons is regarded as a household but not as a family. Thus, some households contain more than one family and some do not contain any families.

Primary family. A family that includes among its members the person who maintains the household.

Wife in husband-wife primary family is a woman living with her husband in a primary family. This category includes women in common-law marriages as well as women in formal marriages.

Geographic regions. The four major regions of the United States, for which data are presented in this report, represent groups of States, as follows:

Northeast: Connecticut, Main, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania Rhode Island, and Vermont.

North Central: Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin.

South: Alabama, Arkansas, Delaware, District of Columbia, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia.

West: Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming.

Metropolitan-nonmetropolitan residence. The population resideing in standard metropolitan statistical areas (SMSA's) constitutes the metropolitan population. Except in New England, an SMSA is a county or group of contiguous counties which contains at least one city of 50,000 inhabitants or more, or "twin cities" with a combined population of a least 50,000. In addition to the county or counties, containing such a city or cities, contiguous counties are included in an SMSA if, according to certain criteria, they are essentially metropoltan in character and are socially and economically integrated with the central county. In New England, SMSA's consist of towns and cities, rather than counties. The metropoltain population in this report is based on SMSA's as defined in the 1970 census and does not include any subsequent additions or changes.

Age. The age classification is based on the age of a woman at her last birthday. Age of woman at first marriage was determined by subtracting the date of birth of the woman from the date of first marriage. Likewise, age of a woman at birth of a child was determined by subtracting the date of birth of the woman from the date of birth of the child.

Race. The population is implicity divided in this report into three groups on the basis of race: White, Black, and "other races." The last category includes persons of any other race except White and Black. The tables in this report show data for all races, Whites, and Blacks.

Spanish origin. Persons of Spanish origin in this report are those persons who indicated that their origin was Mexican, Puerto Rican, Cuban, Central or South American, or some other Spanish origin. The latter category includes persons from Spain as well as persons with combinations of types of Spanish origins. Persons who reported that they were of one of the specific Spanish origin categories and a non-Spanish category were included in the specific Spanish category. Persons of Spanish origin may be of any race.

Years of school completed. Data on years of school completed in this report were derived from the combination of answers to questions concerning the highest grade of school attended by the persons and whether or not that grade was finished. The questions on educational attainment apply only to progress in "regular" schools. Such schools include graded public, private, and parochial elementary and high schools (both junior and senior high), colleges, universities, and professional schools, whether day schools or night schools. Thus, regular schooling is that which may advance a person toward an elementary school certificate or high school diploma, or a college, university, or professional school degree. Schooling in other than regular schools was counted only if the credits obtained were regarded as transferable to a school in the regular school system.

Labor force and employment status. The definitions of labor force and employment status in this report relate to the population 14 years old and over.

Employed. Employed persons comprise (1) all civilians who, during the specified week, did any work at all as paid employees or in their own business or profession, or on their own farm, or who worked 15 hours or more as unpaid workers on a farm or in a business operated by a member of the family, and (2) all those who were not working but who had jobs or businesses from which they were temporarily absent because of illness, bad weather, vacation, or labor-management dispute, or because they were taking time off for personal reasons, whether or not they were paid by their employers for time off, and whether or not they were seeking other jobs. Excluded from the employed group are persons whose only activity consisted of work around the house (such as own home housework, painting or repairing own home, etc.) or volunteer work for religious, charitable, and similar organizatons.

Occupation. Data on occupation are shown for the employed and relate to the job held during the survey week. Persons employed at two or more jobs were reported in the job at which they worked the greatest number of hours during the week. The major groups used here are generally the major groups used in the 1970 Census of Population. The composition of the groups is shown in 1970 Census of Population, Vol. 1, **Characteristics of the Population, Chapter C, General Social and Economic Characteristics, U.S. Summary.**

For this report some of the major occupation groups are combined as follows:

White collar. Professional, technical, and kindred workers; managers and administrators, except farm; sales workers; and clerical and kindred workers.

Blue collar. Craft and kindred workers; operatives, including transport equipment operatives; and laborers, except farm.

Family income. Family income represents the total income of all members of the family. Income, as defined in this report, represents total money income, or the sum of money from wages or salary before deductions for personal taxes and other purposes, net income from self-employment, and income from other sources received by all family members.

In the June 1975 survey, family income was transcribed from information first obtained at the time a household entered the Current Population Survey and updated when it reentered the survey. For about one-fourth of the sample the data are for the year ending in March 1975, and for other fourths the data are for years ending in April, May, and June 1975, respectively.

Income data in this report are based on the respondent's estimate of total family money income in broad, fixed income levels. Previous research has shown that the use of broad income intervals to record money income tends to reduce the rate of nonreporting while increasing the likelihood that the amounts reported will be significantly understated as compared with results from more detailed questions.

Median. The median is the value which divides a distribution into two equal parts; one-half of the cases falling below this value and one-half of the cases exceeding this value.

Symbols. A dash "–" represents zero or a number which rounds to zero. "B" means that the base of a derived measure is less than 75,000, which is too small for the measure to be shown; "NA" means not available; and "X" means not applicable. The symbol ">" denotes less than.

Rounding of estimates. Individual numbers are rounded to the nearest thousand without being adjusted to group totals, which are independently rounded. Derived measures are based on unrounded numbers when possible; otherwise, they are based on the rounded numbers.

SOURCE AND RELIABILITY OF THE ESTIMATES

Source of data. The estimates in this report are based on data obtained from the Bureau of the Census collected in the Current Population Surveys of June 1975 and June 1976 and from Vital Statistics of the United States. The sources of data in each text table and for each figure can be found at the bottom of that table or figure.

The Current Population Survey (CPS) estimates in this report are based on data obtained in June 1975 and, in text table A, June 1976. The monthly CPS deals mainly with labor force data for the civilian noninstitutional population. Questions relating to labor force participation are asked about each member 14 years old and older in each sample household. In addition, supplementary questions are asked each June about fertility and birth expectations of American women.

The CPS sample as of June 1975 was initially selected from the 1970 census file and was updated continuously to reflect new construction where possible (see section "Nonsampling Variability" below). The sample was spread over 461 areas with coverage in each of the 50 States and the District of Columbia. Approximately 47,000 occupied households were eligible for interview each month. Of this number 2,000 occupied units, on the average, are visited but interviews are not obtained because the occupants are not found at home after repeated calls or are unavailable for some other reason. In addition to the 47,000 occupied households, about 8,000 sample units in an average month are visited but found to be vacant or otherwise not to be interviewed.

The estimation procedure used for the monthly CPS data involves inflating the sample results to meet independent estimates of the civilian noninstitutional population of the United States by age, race, and sex. These independent estimates are based on statistics from the decennial census; statistics on birth, deaths, immigration, and emigration; and statistics on the strength of the Armed Forces. Beginning in October 1971, the independent estimates have been based on the 1970 Census of Population.

Reliability of the estimates. Since the CPS estimates in these tables are based on a sample, they may differ somewhat from the figures that would have been obtained if a complete census had been taken using the same schedules, instructions, and enumerators. There are two types of errors possible in an estimate based on a sample survey—sampling and nonsampling. The standard errors provided for this report primarily indicate the magnitude of the sampling error. They also partially measure the effect on some nonsampling errors in response and enumeration, but do not measure any systematic biases in the data. The full extent of nonsampling error is unknown. Consequently, particular care should be exercised in the interpretation of figures based on a relatively small number of cases or on small differences between estimates.

Nonsampling variability. As in any survey work, the results are subject to errors of response and non-reporting in addition to sampling variability. Non-sampling errors can be attributed to many sources, e.g., inability to obtain information about all cases in the sample, definitional difficulties, differences in the interpretation of questions, inability or unwillingness to provide correct information on the part of respondents, inability to recall information, mistakes made in collection such as in recording or coding the data, mistakes made in processing the data, mistakes made in estimating values for missing data, and failure to represent all units (undercoverage). The approximate magnitude of two sources of undercoverage in CPS is known and is described next.

Approximately 600,000 conventional new construction units were issued building permits prior to the 1970 census but building was not completed by the time of the census (i.e., April 1970); these units have no representation in the CPS sample. Conventional new construction, for which building permits were issued after the census, is represented. In addition to undercoverage of conventional new construction, CPS misses at least 200,000 new mobile homes. These are missed because there is no systematic sampling procedure to provide representation of mobile homes constructed since the 1970 census. Note that these estimates of missed units are relevant to the present sample only and not to earlier designs where the extent of undercoverage was generally less.

In addition to the sources of undercoverage in CPS mentioned above, nonresponse is also a source of error with respect to measuring the fertility of American women. Regarding the question on number of children ever born, 8 percent of ever-married women were counted as "not reporting" in the June 1975 CPS Supplement. In these instances numbers of children ever born were imputed, based on matching the nonreporting women with other women of similar racial and age characteristics who did report on children ever born. Tables presenting rates of children ever born are based on all ever-married women in the sample, including women with an imputed, or allocated, value for number of children ever born.

For the study of the spacing of children, the date of a woman's first marriage and the birth dates of her children are essential items of information. These data are also subject to nonresponse, the extent of which is shown in table A-2. A description of the process by which missing dates were allocated is provided below in the section on "Allocation of date of first marriage and birth dates of children."

Except in an experimental portion of the sample, single women were not asked about the number of children born to date in June 1975. In this report rates of children ever born per 1,000 women of all marital statuses combined count single women as childless. This procedure is biased inasmuch as it tends to understate true rates, especially at younger ages at which greater proportions of women are single.

Sampling variability. The standard errors given in the following tables are primarily measures of sampling variability, that is, of the variations that occurred by chance because a sample rather than the whole of the population was surveyed. The chances are about 68 out of 100 that an estimate from the survey differs from a complete census figure by less than the standard error. The chances are about 90 out of 100 that this difference would be less than 1.6 times the standard error and about 95 out of 100 that the difference would be less than twice the standard error.

All the statements of comparison appearing in the text are significant at a 1.6 standard error level or better, and most are significant at a level of more than 2.0 standard errors. This means that for most differences cited in the text, the estimated difference is greater than twice the standard error of the difference. Statements of comparison qualified in some way (e.g., by use of the phrase, "some evidence") have a level of significance between 1.6 and 2.0 standard errors. Comparisons involving data or statements from journal articles or publications not written at the Bureau of the Census do not necessarily meet these statistical standards.

Note when using small estimates. Percent distributions are shown in this report only when the base of the percentage is greater than 75,000. Because of the large standard errors involved, there is little chance that percentages would reveal useful information when computed on smaller bases. Estimated numbers are shown, however, even though the relative standard errors of these numbers are larger than those for the corresponding percentages. These smaller estimates are provided primarily to permit such combinations of the categories as serve each user's needs. Similarly, estimated numbers of children ever born per 1,000 women and birth expectations data are shown in the report only when the associated number of women is greater than 75,000.

Comparability with other data. Data from sources other than the Census Bureau may be subject to both higher sampling and nonsampling variability. In addition, data obtained from the CPS are not entirely comparable with data obtained from other sources. This is due in large part to differences in interviewer training and experiences and in differing survey processes. This is an additional component of error not reflected in the standard error tables. Therefore, caution should be used in comparing results between these different sources.

Standard error tables and their use. In order to derive standard errors that would be applicable to a large number of estimates and could be prepared at a moderate cost, a number of approximations were required. Therefore, instead of providing an individual standard error for each estimate, generalized sets of standard errors are provided for various types of characteristics. As a result, the sets of standard errors provided give an indication of the order of magnitude of the standard error of an estimate rather than the precise standard error.

The figures presented in tables B-1 and B-2 are approximations to standard errors of estimated numbers and estimated percentages. The figures presented in table B-3 are approximations to standard errors of estimated fertility ratios. Estimated standard errors for specific characteristics cannot be obtained from tables B-1, B-2, and B-3 without the use of the factors in table B-4. These factors must be applied to the standard errors in order to adjust for the combined effect of sample design and estimating procedure on the value of the characteristic. Table B-6 contains estimated standard errors for estimates from table B of median age at completion of childbearing for women born from 1900 to 1909. Standard errors for intermediate values not shown in tables B-1, B-2, and B-3 may be approximated by interpolation.

If one chooses, instead of using the standard error and factors tables, standard errors can be computed directly using the formula that follow and the parameters from table B-5. Methods for direct computation are given in the following sections.

Standard errors of estimated numbers. The approximate standard error, σ_x, of an estimated number shown in this report can be obtained in two ways. It may be obtained by use of the formula

$$\sigma_x = f\sigma \qquad (1)$$

where f is the appropriate factor from table B-4 and σ is the standard error of the estimates obtained by interpolation from table B-1. Alternately, standard errors may be approximated by the following formula, (2), from which the standard errors were calculated in table B-1. Use of this formula will provide more accurate results than the use of formula (1) above.

$$\sigma_x = \sqrt{ax^2 + bx} \qquad (2)$$

Here x is the size of the estimate and a and b are the parameters in table B-5 associated with the particular type of characteristic.

Standard errors of estimated percentages. The reliability of an estimated percentage, computed using sample data for both numerator and denominator, depends on both the size of the percentage and the size of the total upon which this percentage is based. Estimated percentages are relatively more reliable than the corresponding estimates of the numerators of the percentages, particularly if the percentages are 50 percent or more. When the numerator and denominator of the percentage are in different categories, use the factor or parameters indicated by the numerator. The approximate standard error, $\sigma_{(x,p)}$, of an estimated percentage, p, on a base of size x can be obtained by use of the formula

$$\sigma_{(x,p)} = f\sigma \qquad (3)$$

In this formula f is the appropriate factor from table B-4 and σ is the standard error on the percentage from table B-2. Alternately, the standard errors may be approximated by the following formula, (4), from which the standard errors in table B-2 were calculated; direct computation will give more accurate results than use of the standard error table and the factors.

$$\sigma_{(x,p)} = \sqrt{\frac{b}{x}(p)(100-p)} \qquad (4)$$

Here x is the size of the subclass of the number of women which is the base of the percentage, p is the percentage ($0 < p < 100$), and b is the parameter in table B-5 associated with the particular type of characteristic in the numerator of the percentage.

Illustration of use of standard error tables. Table 18 of this report shows that in 1975 there were an estimated 2,334,000 ever-married White women born from 1930 to 1939 reporting that they had completed childbearing with two children. Interpolation in table B-1 shows the standard error on an estimate of this size to be approximately 59,000. Applying the appropriate factor from table B-4 and using formula (1) the approximate standard error is 1.00 x 59,000

Table B-1. Standard Errors of Estimated Numbers

(68 chances out of 100. Numbers in thousands)

Size of estimate	Standard error	Size of estimate	Standard error
20...........................	6	2,500......................	61
50...........................	9	5,000......................	82
100.........................	12	10,000....................	115
250.........................	20	25,000....................	160
500.........................	28	50,000....................	189
1,000......................	39		

= 59,000.[1] The chances are 68 out of 100 that the estimate would have been a figure differing from a complete census figure by less than 59,000. The chances are 95 out of 100 that the estimate would have differed from a complete census figure by less than 118,000 (twice the standard error). Table 18 also shows that in 1975 there were 9,833,000 ever-married White women born from 1930 to 1939. Of these 9,833,000 ever-married White women, 2,334,000 or 23.7 percent completed childbearing with two children. Since the numerator of this percentage is the number of White ever-married women, the b parameter from table B-5 is 1567.0337. Using formula (4) the standard error on an estimate of 23.7 percent is approximately:

$$.5 = \sqrt{\frac{1567.0337}{9,833,000}(23.7)(76.3)}$$

Therefore the chances are 68 out of 100 that the estimated 23.7 percent would be within .5 percentage points of a complete census figure. Chances are 95 out of 100 that the estimate would be within 1.0 percentage points of a complete census figure, i.e., the 95-percent confidence interval would be from 22.7 to 24.7 percent.

Standard error of a difference. For a difference between two sample estimates, the standard error is approximately equal to

$$\sigma_{(x-y)} = \sqrt{\sigma_x^2 + \sigma_y^2} \qquad (5)$$

where σ_x and σ_y are the standard errors of the estimates x and y; the estimates can be of numbers, percents, ratios, etc. This will represent the actual standard error quite accurately for the difference between two estimates of the same characteristic in two different areas, or for the difference between separate and uncorrelated characteristics in the same area. If, however, there is a high positive correlation between the two characteristics, the formula will overestimate the true standard error.

Illustration of the computation of the standard error of a difference between estimated percentages. Table 18 also shows that in 1975 there were an estimated 2,261,000 or 25.8 percent of the 8,751,000 ever-married White women born from 1910 to 1919 reporting that they had completed childbearing with two children, while, as shown above, for ever-married White women born from 1930 to 1939, the corresponding percentage is 23.7 percent. The standard error (σ_x) on 23.7 percent is .5 percentage points, as shown above. Using formula (4) and the b parameter for the number of women from table B-5, the standard error (σ_y) on 25.8 percent is approximately .6 percentage points. Therefore, using formula (5), the standard error of the estimated difference of 2.1 percent is about

$$.8 = \sqrt{(.5)^2 + (.6)^2}$$

This means the chances are 68 out of 100 that the estimated differences based on sample estimates would vary from the difference derived using complete census figures by less than .8 percent. The 68-percent confidence interval about the 2.1 percent difference is from 1.3 to 2.9, i.e., 2.1 ± .8. A conclusion that the average estimate of the difference derived from all possible samples of the same size and design lies within a range computed in this way would be correct for roughly 68 percent of all possible samples. The 95-percent confidence interval for the estimated difference of 2.1 percent is: 2.1 ± 1.6, or from .5 to 3.7 percent. Since this confidence interval does not include a difference of zero, we can conclude with 95-percent confidence that there is a difference between the

Table B-2. Standard Errors of Estimated Percentages

(68 chances out of 100)

Base of estimated percentage (thousands)	Estimated percentage					
	1 or 99	2 or 98	5 or 95	10 or 90	25 or 75	50
100	1.2	1.7	2.7	3.7	5.4	6.2

---

[1] Formula (2) gives a standard error of 60,000.

percentages of ever-married White women completing childbearing with two children for women married from 1910 to 1919 and for women married from 1930 to 1939.

Standard error of a fertility ratio. A separate standard error table, table B-3, provides standard errors for both number of children ever born and number of expected lifetime births per 1,000 women. The sampling variability on the ratio of children born per 1,000 women depends on the shape of the distribution on which the ratio is based, the size of the sample, the sample design and the use of ratio estimates. Table B-3 was formed by using the following equation:

$$\sigma_{(1,000x)} = \frac{FR}{N}\sqrt{\Sigma n^2 x_n - \frac{(\Sigma n x_n)2}{N}}$$

where $\sigma(1,000x)$	is the standard error of a fertility ratio per 1,000 women (1,000x)
R	is a constant which depends upon the size of the sample. For 1975 $R = 1,000\sqrt{1,170} = 34,200$
n	is the specific number of children ever born or expected (n = 0,1,2,3,4,5,6,7 +)
x_n	is the estimated number of women who have n children ever born or expected,
N	is the total number of women $= \sum_{n=0}^{7+} x_n$, and
F	is dependent on the particular sample design used for this survey and is also a function of the magnitude of the ratio of children ever born or expected per 1,000 women. The values of F used in compiling table B-3 are as follows:

F for Children Ever Born or Expected Per 1,000 Women

Number of children per 1,000 women	F
500	1.05
1,000	1.14
1,500	1.18
2,000	1.22
2,500	1.26
3,000	1.30
3,500	1.34
4,000	1.38

Note about fertility ratios of a particular order. Many fertility ratios in this report are for births of a particular order, i.e., first births per 1,000 women ever married, seconds births per 1,000 women, etc. To determine standard errors for this kind of statistics, table B-2 the table of standard errors of percentages, should be used (with the ratio adjusted to a per-100 basis when ratios are on a per-1,000 basis). For data involving two or more possible events per woman, table B-3, the table of standard errors of estimated fertility ratios, should be used.

Table B-3. **Standard Errors of Estimated Fertility Ratios**

(68 chances out of 100)

Number of women (thousands)	Children ever born or expected per 1,000 women							
	500	1,000	1,500	2,000	2,500	3,000	3,500	4,000
250	51	93	129	164	198	234	274	315
500	36	66	92	116	140	166	194	222
750	30	54	74	95	114	135	158	181
1,000	26	47	65	82	99	117	137	138
2,000	18	33	45	58	70	83	97	112
5,000	11	20	29	37	44	52	61	70
10,000	9	15	20	26	31	38	44	30
15,000	7	12	16	21	26	29	35	41
20,000	6	11	15	19	23	27	31	33
25,000	5	9	12	16	20	24	28	32

Illustration of the compution of the standard error of a fertility ratio. Table 29 of this report shows that for Spanish origin women first married from 1960 to 1964, the total births within 24 months of their first marriage is 1,146 per 1,000 wives. Table 29 also shows that there were 350,000 wives in this group. Table B-3 shows the standard error of a ratio of 1,146 births on a base of 350,000 women to be approximately 92.[2] Multiplying the standard error of 92 by 1.24 (the factor for Spanish origin women found in table B-4), the standard error becomes 114 per 1,000 women. Consequently, the chances are 68 out of 100 that the estimate would have been a fertility ratio differing from a complete census figure by less than 114 per 1,000. The chances are 95 out of 100 that the estimate would have been a fertility ratio differing from a complete census figure by less than 228 per 1,000 (twice the standard error), i.e., this 95-percent confidence interval would be between 918 and 1,374 births per 1,000 Spanish origin women occuring within 24 months of their first marriage, for these women first married from 1960 to 1964.

The standard errors of estimated numbers as calculated for this report are not applicable to estimates of total women by age or race. As estimates by age, sex, and race are independently derived totals, they are not subject to any sampling error. Because of the use of ratio estimation, any published number which is a large subset of a given age-sex-race group (i.e., 50 percent or more) will have a sampling error to the standard errors can be obtained by using the population of the age-sex-race group as the base of the percentage and converting the standard errors in table B-2 from percentages to numbers by multiplying them by the bases. For example, table 17 of this report shows that in June 1975 there were 11,278,000 women ever-married born between 1930 to 1939. If this figure were a subset of a considerably larger independent age-race group, the standard error on this estimate should be taken from table B-1. However, since the figure of 11,278,000 ever-married women born from 1930 to 1939 represents approximately 95.6 percent of the 11,796,000 total women born from 1930 to 1939, a close approximation to the sampling error of the figure can be obtained using table B-2. The standard error of 95.6 percent on a base of 11,796,000 is approximately .3 percent. Thus the standard error of 11,278,000 would be 11,796,000 multiplied by .003, or about 35,000. Consequently, the chances are 68 out of 100 that the estimate would have been a figure differing from a complete census figure by less than 35,000. The chances are 95 out of 100 that the estimate would have been a figure differing from a complete census figure by less than 70,000 (twice the standard error).

Standard error of a median. The sampling variability of an estimated median depends upon the form of the distribution as well as the size of its base. An approximate method for measuring the reliability of a median is to determine an interval about the estimated median, such that there is a stated degree of confidence that the median based on a complete census lies within the interval. The following procedure may be used to estimate confidence limits of a median based on sample data:

(1) Determine, using the standard error tables and factors or formula (4), the standard error of an estimate of 50 percent from the distribution.
(2) add to and subtract from 50 percent the standard error determined in step (1).
(3) using the distribution of the characteristic, calculate the confidence interval corresponding to the two points established in step (2).

A two-standard-error confidence interval may be determined by finding the values corresponding to 50 percent plus and minus twice the standard error determined in step (1).

Note: When combining two or more distributions the median of the distribution must be computed by the user. The median is the estimate for the woman at the center of the distribution and may be approximated by linear interpolation within the group which contains this woman.

Table B-4. "f" Factors to be Applied to Generalized Standard Errors in Tables B-1, B-2, and B-3

Type of characteristic	"f" factors for persons
CPS, total, White or Black women[1]	1.00
CPS, Spanish origin women[1]	1.24
CPS, farm women	1.38

[1] Apply a factor of 1.41 to these factors for metropolitan or nonmetropolitan characteristics.

Table B-5. "a" and "b" Parameters for Estimated Numbers and Percentages of Women

Characteristics	Parameters	
	a	b
CPS, number of women[1]	-0.000018	1567.0337
CPS, Spanish origin women[1]	-0.000033	2396.7828
CPS, farm women	-0.000322	2993.0344

[1] Apply a factor of 2 to these parameters for metropolitan or nonmetropolitan characteristics.

---

[2] Determined by interpolation and rounding to the same accuracy as in the table.

Illustration of the computation of a confidence interval for a median. Table 17 of this report shows that in 1975 the median age of completion of childbearing for all mothers born between 1920 to 1929 was estimated to be 31.2 years. Table 17 also indicates the base of the distribution from which this median was determined is 10,584,000 mothers.

1. Using formula (4) the standard error of 50 percent on a base of 10,584,000 is about .61 percent.
2. To obtain a 95-percent confidence interval on an estimated median add to and subtract from 50 percent twice the standard error found in step (1). This yields percent limits of 48.78 and 51.22.
3. From table 17, 45.5 percent of mothers had completed childbearing by the middle of their 30th year and 6.4 percent had completed childbearing between their 30.5 and 31.5 year. By linear interpolation, the lower limit on the estimate is found to be about

$$30.5 + (31.5-30.5)\frac{(48.78-45.50)}{6.40} \approx 31.0$$

Similarly, the upper limit may be found by linear interpolation to be about

$$30.5 + (31.5-30.5)\frac{(51.22-45.50)}{6.40} \approx 31.4$$

Thus, the 95-percent confidence interval on the estimated median is from 31.0 years to 31.4 years.

Appendix C

ALLOCATION OF DATE OF FIRST MARRIAGE AND BIRTH DATES OF CHILDREN

In the June 1975 Current Population Survey, month and year of first marriage were not reported for 11.9 percent of ever-married women; an additional 1.2 percent of the women had a report for year of first marriage, but not month (table A-1). With respect to the birth dates of children, neither month nor year of birth was reported for 19.7 percent of the children born to women in the survey (table A-2), of which almost one-third was due to the fact that women with more than 5 children were not asked to report date of birth for all of their children. For an additional 0.9 percent of the children year of birth was reported, but not month.

Where only the month of first marriage or of a child's birth was missing, a month was assigned in rotation. When both month and year of the event were missing, dates were allocated by assigning the date(s) in question from the corresponding dates of the women of matched characteristics whose record was most recently processed in the computer editing procedures and for whom data were fully reported.

The June 1975 Current Population Survey obtained date of birth for a maximum of five children, namely, the three oldest and two youngest. Therefore, for women with six or more children ever born, information was missing for any child born between the third oldest and the second youngest. Date of birth was allocated to these children by spacing them at equal intervals between the third oldest and second youngest. For example, if a woman had seven children ever born with the third oldest being 125 months old and the second youngest being 50 months old, the fourth and fifth children (for whom no date of birth would have been obtained) would be assigned a month and year of birth that would correspond to ages 100 months and 75 months as of July 1, 1975.

ADJUSTMENT OF DATA FOR INCOMPLETE COHORT EXPERIENCE

In tables 1 to 19 and 26 to 35, rates have been adjusted where only a part of the cohort has attained the stated age or the stated interval since marriage. Such data are footnoted in the tables to indicate that they have been adjusted. The adjustment was made in order to make maximum use of information available and to obtain rates that would be comparable with those for older cohorts of women. Without the adjustment, the rates in question would be too low for proper comparison with those of older cohorts. The adjustments were made according to the principles explained below in terms of children born to a marriage cohort of women; a similar technique was used for birth cohorts of women.

As an example, consider two women belonging to the first marriage cohort of 1960 to 1964, one first married in January 1960 and the other first married in December 1964. The first had been married 185 complete months by the time of the June 1975 survey, whereas the second had been married only 126 complete months by the time of the survey. (Women first married in other months in the 1960 to 1964 calendar period had been married some number of months between the two extremes cited above.)

Also consider the fact that marriage cohort data in this report were tabulated in terms of months from first marriage of the mother to the birth of a child. One such spacing period tabulated is the broad interval "121 to 180 months." It follows that for this broad interval the woman first married in January 1960 has been married long enough (185 months) to have been at risk of childbearing throughout the entire interval and therefore to have contributed fully to the data tabulated for the cohort, whereas the woman first married in December 1964 was at risk of childbearing for only a part of the interval, that is, from 121 to 126 months. In fact, any woman married after June 1960 was not married long enough to have been at risk of childbearing for the full 121-to-180-month interval after first marriage.

The adjustment made for the incomplete experience of some women in the marriage cohort will make the following assumptions: (1) Women who first married in the calendar year period 1960 to 1964 did so in equal numbers in each of the 60 months from January 1960 to December 1964; (2) the future childbearing experience of those who were not at risk of childbearing throughout the complete interval will be the same as that of those who were at risk for the entire interval.

To obtain an adjustment proportion for a broad tabulation interval, such as 121 to 180 months, where a portion of the women have not been at risk for the entire interval, determine the proportions of the women who were at risk during each month in the interval. In the example above, all women in the 1960 to 1964 cohort were at risk of childbearing for at least 121 months after marriage. On the other hand, only those women in the cohort whose first marriage occurred in January to June 1960 were at risk for the entire interval of 121 to 180 months after first marriage. The *average* proportion of women at risk of childbearing in the interval can be calculated, and the reciprocal is the desired adjustment factor for the interval in question. The following illustrates the procedure for the 121-to-180-month interval for the marriage cohort of 1960 to 1964:

Interval (months)	Proportion of women in cohort contributing experience to the interval
121.	60/60 (all women at risk)
122.	60/60 (all women at risk)
126.	60/60 (all women at risk)
127.	59/60 (women married in Dec. 1964 not at risk)
128.	58/60 (women married in Nov. and Dec. 1964 not at risk)
179.	7/60 (women married after July 1960 not at risk)
180.	6/60 (women married after June 1960 not at risk)

Average proportion 35.25/60

Adjustment factor = 60/35.25 = 1.702

Two examples of the effect of the adjustments are given below. The first example illustrates how the adjustment factor and the distribution of births are related to the proportion of births that are imputed. The second example illustrates how the adjustments actually were made.

The births tabulated for the interval 121 to 180 months for the 1960 to 1964 marriage cohort were multiplied by the adjustment factor of 1.702 and added to births at intervals prior to 121 months to obtain the cumulated births through 180 months.

First example: Table 27 shows that White women first married in 1960 to 1964 had 2,288 total births per 1,000 women by 120 months after marriage. There is no footnote attached to that rate in table 27, because no adjustment was needed up to that interval. The same group of women had an adjusted rate of 2,539 by 180 months after marriage; a footnote attached to the rate indicates that the rate was adjusted. Subtraction of 2,288 from 2,539 yields an estimate of 251 births per 1,000 women occurring in the interval from 121 to 180 months. Division of 251 by the adjustment factor of 1.702 for this marriage cohort in the 121 to 180 month interval yields an estimate of 147 births per 1,000 women on an unadjusted basis for the interval. Addition of 147 to the cumulated rate of 2,288 for the 120 month interval produces

Table C-1. Calculations: Total Births to White Women First Married in 1970 to 1974

(For meaning of symbols, see text)

Interval since first marriage	Uncumulated			Cumulated			
	Unadjusted number (a)	Adjustment factor (b)	Adjusted number (a) x (b) (c)	Unadjusted number (d)	Adjusted number (e)	Ratio of adjusted to unadjusted births (e) ÷ (d) (f)	Rate shown in table 27 $\frac{1000\ (e)}{6,896}$ (g)

TOTAL BIRTHS IN SPECIFIED INTERVAL							
Before marriage:							
31 months and over................	219	1.000	219	219	219	1.000	32
25 to 30 months..................	83	1.000	83	302	302	1.000	44
13 to 24 months..................	97	1.000	97	399	399	1.000	58
1 to 12 months...................	199	1.000	199	598	598	1.000	87
After first marriage:							
0 to 5 months....................	440	1.000	440	1,038	1,038	1.000	(1)
6 months.........................	239	1.000	239	1,277	1,277	1.000	185
7 months.........................	220	1.017	224	1,497	1,501	1.003	(1)
8 months.........................	158	1.034	163	1,655	1,664	1.005	(1)
9 months.........................	166	1.053	175	1,821	1,839	1.010	267
10 months........................	156	1.071	167	1,977	2,006	1.015	291
11 and 12 months.................	276	1.101	304	2,253	2,310	1.025	335
13 and 14 months.................	193	1.143	221	2,446	2,531	1.035	367
15 and 16 months.................	205	1.188	243	2,651	2,774	1.046	402
17 and 18 months.................	205	1.237	254	2,856	3,028	1.060	439
19 and 20 months.................	162	1.290	209	3,018	3,236	1.073	469
21 and 22 months.................	158	1.348	213	3,176	3,450	1.086	500
23 and 24 months.................	168	1.412	237	3,344	3,687	1.103	535
25 to 30 months..................	445	1.558	694	3,789	4,381	1.156	635
31 to 36 months..................	381	1.846	704	4,170	5,085	1.219	737

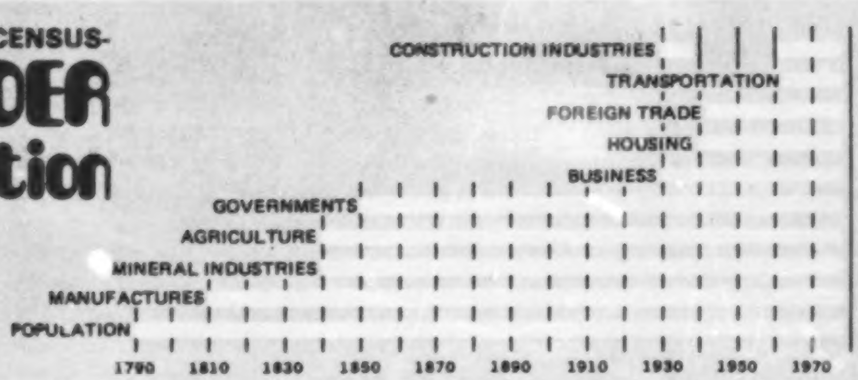
[1] Rate not shown in table 27.

an estimated rate of 2,435 for the unadjusted cumulation to 180 months. The effect of the adjustment is then seen by dividing the adjusted cumulated rate (2,539) by the unadjusted cumulated rate (2,435); the result is 1.043, which means that 4.3 percent of the births in the adjusted rate were imputed.

Second example: The most extensive series of adjustments for incomplete cohort experience involves the cohort of women who first married in 1970 to 1974. Table C-1 shows the computations actually made for White women first married in 1970 to 1974 to arrive at the rates of total births shown in table 27.

U.S. BUREAU OF THE CENSUS-

FACTFINDER for the Nation



FACTFINDER FOR THE NATION

A new series of brochures, geared for the general reader as well as the potential user of Census Bureau data, that replaces the single *Factfinder* issued in 1970. Published periodically, each new *Factfinder* covers some particular aspect of the Bureau's work.

Each brochure has 4 pages, except No. 4, "History and Organization" (12 pages) and No. 5, "Reference Sources" (8 pages).

Series subscription, Nos. CFF 1-17, as issued, $3.25, or $1.50 for CFF 9-17 alone. Individual copies, $0.25 each, except No. 4 ($0.30). Discount of 25 percent on orders of 100 copies or more sent to one address.

CFF No.	Title	Issued
